* We are grateful to Mari Sako and Chris Flegg of the University of Oxford's Saïd Business School and to the late Mark Janes of the University of Oxford's Bodleian Library for time and resources helpful to this research, and we thank Alexander Kranz and David Tibbals for outstanding research assistance. We received helpful comments, criticisms and suggestions from Phil Keefer. All errors are ours.

Credit Rating Agencies and Political Budget Cycle Dynamics Around the World

Abstract

Recent research suggests that credit rating agencies (CRAs) discipline incumbent governments that are otherwise given to increase budget deficits in election periods so that they can signal economic policy competence, temporarily increase economic growth, and attract more voter support at the polls. We propose what those disciplining mechanisms are –sovereign rating (rating) downgrades or heightened threats of downgrade that undercut incumbent claims of economic policy competence and increase the cost of credit— and then investigate evidence related to those propositions in analyses of ratings by major CRAs, budget balances, and election outcomes for 63 countries holding 111 national executive elections from 2002-2011. We find that: 1) incumbents going into an election year immediately after a rating downgrade are 27 percentage points more likely to lose at the polls; and 2) incumbents going into an election year with a negative rating outlook indicating a higher likelihood of near-term downgrade run smaller budget deficits than when incumbent rating outlooks are stable or positive. Ratings act like fiscal policy rules disciplining incumbents when they are more vulnerable to budgetary spending sprees for short-term electoral gain rather than longer-term economic growth and development. Negative outlooks signal potential and downgrades actual rules violations that election-year incumbents have incentives to avoid by maintaining responsible fiscal policies.

Key words: Credit rating agencies, fiscal policy, budget deficits, elections, regulation

1. Introduction

This study investigates whether and how private, for-profit credit rating agencies (CRAs) influence the fiscal policy of national incumbent governments in developed and developing democracies during election periods. It is axiomatic that fiscal policy discretion empowers national governments to provide public services critical to long-term economic growth and short-term popular support. Flexible taxing and spending policies let governments finance public infrastructure like roads and bridges as well as social programs like healthcare and retirement insurance, both designed to increase productivity, protect against catastrophic risk, and promote faster long-term economic growth and poverty reduction. Such fiscal policy levers take on greater importance during recessions when expansionary fiscal policies let governments engage in deficit spending to finance public infrastructure and social programs temporarily boosting lagging demand.

But fiscal policy also has short-term, politically-opportunistic dimensions often revealing themselves in democracies during elections. Research reaching back at least as far back as Nordhaus (1975) and Rogoff and Siebert (1988), running through Drazen and Eslava (2010) and others (*e.g.*, Bernhard, Chorzempa, Riley, and Vaaler, 2015) has theoretically-modeled and empirically-documented evidence of so-called “political budget cycles” (PBCs) where incumbent governments have incentives to run larger budget deficits during election periods. With the exception of Rogoff (1990), the academic literature on PBCs maintains that governments pursue expansionary fiscal policy (increase spending or raise taxes) with a short-term view toward winning elections, rather than maximizing the longer-term national welfare function. Most recently, Hanusch and Keefer (2014) demonstrate that inefficient expenditure for outright vote buying is especially pronounced in countries where parties have not managed to organize around programmatic platforms, thus forcing incumbents to provide election gifts to strategic constituencies.

Curtailed spending, increased taxation, and other contractionary fiscal policies typically follow this election-induced fiscal expansion. In developing democracies, post-election periods may also bring increased likelihood of speculative attacks on local currencies (Leblang, 2002), decreased foreign investment (Vaaler, 2008), decreased foreign lending (Bernhard *et al.*, 2015) and higher-priced credit on foreign lending (Block and Vaaler, 2004). Together, such pre- and post-election PBC dynamics can slow long-term economic growth and poverty reduction processes, and raise the likelihood of economic crises leading to costly re-scheduling or outright default on payment of government (sovereign) debt (Hatchondo and Martinez, 2010).

Distinguishing between fiscal policies supporting long-term national welfare and short-term political interests can be difficult, but at least one group of prominent foreign financial actors, CRAs like Moody’s Investor Services (Moody’s), Standard and Poor’s Credit Rating (S&P), and Fitch Credit Rating (Fitch), have strong incentives to make such distinctions and state them publicly. CRAs profit from publishing standardized letter-grade ordinal rankings (*e.g.*, AAA) indicating the likelihood that sovereign governments will meet their financial obligations to lenders, particularly foreign banks and bondholders. Such ratings summarize CRA assessments of government fidelity to creditor interests prioritizing complete and timely payment of interest and principle under loan agreement terms. In a broader sense, such ratings represent public “grades” on the sustainability of incumbent fiscal policies.

Their grades matter for incumbents required by U.S. and international regulation to obtain ratings to place debt with institutional investors (White, 2010). Their grades matter for banks and bondholders that use ratings to price credit and set country lending limits (Bernhard *et al.*, 2015; Cantor and Packer, 1997; Larraín, Reisen, and von Maltzen Pacheco, 1997). Their grades matter for prominent media figures, who describe CRAs as financial “superpowers” (Friedman, 1996) and incumbent politicians, who connect electoral success with success in maintaining a favorable rating (*Guardian*, 2012).

But perhaps ratings do more than merely grade incumbent fiscal policies during election periods. Perhaps inadvertently, ratings also influence those fiscal policies. Our intuition follows from recent research (Hanusch and Vaaler, 2013) analyzing panel data on ratings, elections and budget balances for 18 developing democracies from 1990-2004 and documenting a positive relationship between election-year ratings and budget balances: higher ratings meant smaller budget deficits, sometimes even surpluses during elections. We build on that study by investigating how and why ratings decrease those election-year budget deficits.

The underlying intuition is simple. CRAs grow more concerned about incumbent ability and willingness to fulfill its financial obligations –make timely interest and principal payments on sovereign bonds and bank loans— when incumbents engage in inefficient electoral spending sprees. CRAs then become more likely to decrease incumbent ratings indicating deteriorating creditworthiness. Such changes affect the cost of financing future fiscal deficits as financial markets re-price in the risk of default, which, as we show, is closely correlated with the CRA ratings. When CRAs decrease ratings there is also likely to be a more immediate electoral effect. Previous research demonstrates that voters are more likely to punish governments for election-induced fiscal expansions when they have better access to information on the national budget (Alt and Lassen 2006, Shi and Svensson 2006). CRAs provide that information and thus render an incumbent more likely to lose an election if downgraded during an election period.

In this context, ratings function like other fiscal rules limiting the magnitude of political budget cycles (Rose 2009). CRAs assess incumbents with their ordinal rating levels running from the incumbents meeting the most demanding fiscal rule to less demanding rules represented by descending ordinal letter grades (AAA, AA-, AA, A+, A, A-, BBB+, BBB, BBB-, BB+, BB, BB-, B+, B, B-, C and lower). Incumbents prefer to ascend rather than descend these ordinal ranks. With each letter grade increase, incumbents commit to decreasing inefficient expenditure to buy votes during election periods. Ratings may not have the force of law that other constraints on sovereign borrowing do when enshrined in regulatory, legislative or even constitutional provisions. But ratings can act like soft constraints initially imposed and periodically revised by CRAs with similarly negative implications for incumbents threatening their violation during election periods.

We analyze evidence related to this intuition in a sample of 111 presidential and parliamentary elections held in up to 63 developing and developed democracies from 2002 to 2011. The evidence helps us test two hypotheses: 1) that incumbents suffering recent downgrades going into election periods are more likely to lose at the polls; and 2) that incumbents facing a heightened threat of downgrade, evidenced by rating with a negative outlook going into election periods, borrow less. Section 2 reports empirical methods used to test these two hypotheses. Section 3 reports analytical results indicating support for both hypotheses. Section 4 concludes with a discussion of key results and their implications for research and policy on the disciplinary impact of ratings on incumbents.

2. Analytical Model Terms, Data Sources, Sampling and Estimation Strategies

2.1. CRA Downgrade and Incumbent Turnover Analyses

All model terms used in our analyses are listed in Table 1. This table also includes information on measurement, data sources and descriptive statistics. To test whether downgrades render incumbents more vulnerable to electoral turnover, we first define our dependent variable, *Incumbent Turnover*, as a 0-1 dummy taking the value of 1 if the largest incumbent party is not re-elected and 0 otherwise. We source data for this dependent variable from the World Bank's Database of Political Institutions (DPI) (Beck Clarke, Groff, Keefer, and Walsh, 2001), which identifies the largest incumbent party in parliamentary systems and the incumbent party or largest executive coalition party in a presidential system.

The main independent variable in all incumbent turnover analyses (ITA in Table 1), *Downgrade*, is also a 0-1 dummy, this time taking the value of 1 if, in the year prior to the election year, the incumbent had been downgraded at least one ordinal rating level by a least one of three CRAs: Moody's, Fitch, and S&P. We also include a 1-year lagged value of *Downgrade* to compare and contrast with immediate prior-year effects. We source data for these independent variables from Bloomberg International, which lists the history of CRA sovereign "ceiling" ratings for long-term foreign currency-denominated financial obligations incurred by countries around the world. Table 2 below lists the ordinal letter-grade ratings for all three CRAs along with their common interpretation regarding sovereign creditworthiness. We convert those letter-grade ordinal ratings to 0-16 numerical ratings for analytical convenience.

TABLE 1: Variable names, measures, predicted impacts, data source and descriptive statistics

Variable Category	Variable Name	Variable Measurement	Predicted Variable Impact on Dependent Variable (+, -)	Variable Source and Descriptive Statistics
Dependent Variables	<i>Primary Budget Balance</i>	General government revenue minus expenditure, excluding interest payments, as a percentage of GDP.	Incumbent turnover analyses (ITA): Incumbent governments (incumbents) running more positive primary budget balance in election years are less likely to turn over after election (-); Budget balance analyses (BBA): Dependent variable.	IMF WEO Mean ITA: -0.35 Std Dev ITA: 4.13 Mean BBA: -0.37 Std Dev BBA: 4.20
	<i>Overall Budget Balance</i>	General government revenue minus expenditure as a percentage of GDP.	Same as for <i>Primary Budget Balance</i> .	IMF WEO Mean ITA: -2.36 Std Dev ITA: 4.68 Mean BBA: -2.24 Std Dev BBA: 4.53
	<i>Incumbent Turnover</i>	0-1 indicator taking the value of 1 when the incumbent loses an election, otherwise 0.	ITA: Dependent variable.	DPI Mean ITA: 0.52 Std Dev ITA: 0.50
Control Variables	<i>Unified Government</i>	0-1 indicator taking the value of 1 when the dominant party in the legislature is the incumbents, 0 otherwise.	ITA: Ambiguous –incumbents aligned with legislature run more negative budget balances in election periods thus increasing turnover likelihood (+), but have more control over electoral process thus decreasing turnover likelihood (-); BBA: Incumbents aligned with legislature run more negative budget balances (-).	DPI Mean ITA: 0.24 Std Dev ITA: 0.43 Mean BBA: 0.31 Std Dev BBA: 0.46
	<i>Parliamentary System</i>	0-1 indicating taking the value of 1 when the country system is parliamentary (not presidential).	ITA: Parliamentary system incumbents have more control over electoral processes decreasing turnover likelihood (-); BBA: Parliamentary system incumbents run more negative budget balances (-).	DPI Mean ITA: 0.70 Std Dev ITA: 0.46 Mean BBA: 0.66 Std Dev BBA: 0.47
	<i>GDP Growth</i>	Annual percentage growth of GDP adjusted for inflation.	ITA: Incumbents in countries with faster economic growth have lower turnover likelihood (-); BBA: Incumbents in countries with faster economic growth run less negative budget balances (+).	WDI Mean ITA: 3.14 Std Dev ITA: 3.33 Mean BBA: 3.08 Std Dev BBA: 3.51
	<i>Ln GDP Per Capita</i>	Natural log of GDP per capita	ITA: Incumbents in countries with larger per capita GDP have lower turnover likelihood (-); BBA: Incumbents in countries with larger per capita GDP run less negative budget balances (+).	WDI Mean ITA: 9.58 Std Dev ITA: 0.99 Mean BBA: 9.45 Std Dev BBA: 1.06
	<i>Public Debt</i>	Stock of direct government fixed-term contractual obligations to others outstanding on a particular date, usually the beginning of the country's fiscal year, as a percentage of GDP.	ITA: Incumbents in countries with larger Public Debt have higher turnover likelihood (+); BBA: Incumbents in countries with larger Public Debt run more negative budget balances (-).	WDI Mean ITA: 50.11 Std Dev ITA: 28.22 Mean BBA: 49.18 Std Dev BBA: 29.11
Main Variables	<i>Rating</i>	Average of up to three ceiling ratings of sovereign creditworthiness for long-term foreign currency denominated debt (from Moody's, S&P and Fitch), stated on a 0-16 scale (See Table 2).	ITA: Incumbents in countries with higher credit rating have lower turnover likelihood (-); BBA: Incumbents in countries with higher credit rating run less (more) negative budget balances in election years (+) (non-election years (-)).	Bloomberg Mean ITA: 10.92 Std Dev ITA: 4.66 Mean BBA: 10.44 Std Dev BBA: 4.77
	<i>Downgrade Stable Upgrade</i>	0-1 indicator taking the value of 1 when a rating decreases (D), remains the same (S) or increases (U) compared to the previous year.	ITA: Upgrades and stable ratings have negative effect on turnover (-). Downgrades have a positive effect on government turnover (+).	Bloomberg Mean ITA: 0.09 (D); 0.63 (S); 0.28 (U) Std Dev ITA: 0.29 (D); 0.45 (S); 0.48 (U)
	<i>Election Year</i>	0-1 indicator taking the value of 1 when it is an election year.	BBA: Incumbents borrow more in election years (-).	DPI Mean BBA 0.25 Std Dev BBA: 0.43
	<i>Election Positive Election Stable Election Negative</i>	Three separate 0-1 indicators taking the value of 1 when it is election year and the rating has a positive (<i>Election Positive</i>), stable (<i>Election Stable</i>) or negative (<i>Election Negative</i>) watch or outlook.	BBA: Incumbents with positive and stable ratings borrow more in election years (-); governments with negative ratings do not borrow more than usual in election years (+).	Bloomberg and DPI Mean BBA: 0.04 (EP); 0.17 (ES); 0.05 (EN) Std Dev BBA: 0.20 (EP); 0.37 (ES); 0.21 (EN)

We sample ratings only from these three CRAs. We previously noted that CRAs derive their importance in sovereign borrowing in part because of regulatory requirements in the US and elsewhere (*e.g.*, the United Kingdom) requiring ratings to place debt offerings with institutional investors such as mutual and pension funds. At least 12 US federal regulations promulgated between 1931 and 1994 required borrowers, sovereign or otherwise, to seek ratings from CRAs deemed by the US Securities Exchange Commission to be Nationally Recognized Statistical Rating Organizations (NRSROs). Additional regulatory reform in the wake of the 2007-2008 financial crisis arguably increased the financial regulatory role of CRAs despite their apparent failure to anticipate the crisis and mitigate its negative economic effects. These regulations and the broader history of CRAs in US and international financial regulation are discussed in Cantor and Packer (1997) and White (2010).

TABLE 2: CRA ratings, numerical equivalents and interpretations

Moody's	S&P and Fitch	Grade	Numerical Equivalent on 0-16 Scale	Common Interpretation
Aaa	AAA	Investment	16	Extremely strong capacity to meet its financial obligations.
Aa1	AA+		15	
Aa2	AA		14	
Aa3	AA-	Investment	13	Very strong capacity to meet its financial obligations.
A1	A+		12	
A2	A		11	
A3	A-	Investment	10	Adequate capacity to meet its financial obligations.
Baa1	BBB+		9	
Baa2	BBB		8	
Baa3	BBB-	Investment	7	Less vulnerable than lower rated obligors but facing adverse conditions which could lead to obligor's inadequate capacity to meet its financial obligations.
Ba1	BB+		6	
Ba2	BB		5	
Ba3	BB-	Speculative (Junk)	4	More vulnerable than the obligors rated above. Obligor currently has the capacity to meet its financial obligations but adverse conditions will likely impair this capacity.
B1	B+		3	
B2	B		2	
B3	B-	Speculative (Junk)	1	Currently vulnerable and dependent on favorable conditions to meet its financial obligations.
C	C		0	

CRA watch/outlook (within rating level) and interpretation

Positive Outlook: Potential upgrade in next two years
Stable Outlook: Neither potential upgrade nor downgrade in next two years
Negative Outlook: Potential downgrade in next two years

Moody's, S&P and Fitch are three original NRSRO CRAs active in the sovereign rating business. Even after post-crisis regulatory reforms in the 2010s, reforms that mandated the introduction of new CRAs with NRSRO status, Moody's, S&P and Fitch still dominate as the only three CRAs with global ratings coverage of sovereign and sub-sovereign (*e.g.*, corporate) borrowers. Since the late 1990s, these three have comprised about 95% of the global market for ratings work, and not withstanding their apparent miscues in 2007-2008, continue to enjoy a reputation for high-quality assessments of creditworthiness on which investors around the world rely (CFR, 2015; White, 2010). For these reasons, we limit our sampling to ratings from these three CRAs.

We sample only from ratings based on foreign-currency denominated obligations because they are the dominant public financing instruments in many countries, particularly in the developing world. They are more popular for foreign institutional investors, and thus find more coverage among

financial analysts and the media. We code *Downgrade* as a 1 even if only one of the three CRAs downgrade an incumbent without others immediately following, as in the case of S&P's downgrade of the US in August 2011. Even a downgrade by one of the three CRAs can generate substantial financial market or broader popular response. During the 2012 US presidential election campaign, Republican critics of US President Barack Obama referred to him derisively as "President Downgrade" (e.g., Mittromneycentral.com, 2011). It is also possible that a downgrade by one CRA might conflict with an upgrade by another, though we find no such instances in our sample. In the longer term, ratings by the three CRAs show substantial convergence around a single ordinal level (White, 2010).

Other controls include *GDP Growth*, which is the annual percentage growth rate in gross domestic product (GDP). Consistent with the literature on economic voting (e.g. Duch and Stevenson 2008), faster economic growth increases the likelihood of incumbent re-election. *Ln GDP Per Capita* is the natural log of GDP per capita. Wealthier countries are less likely to turn out incumbents. These data are sourced from the World Bank's World Development Indicators (WDI). We also control for *Government Debt*, which is the total value of the general government's financial obligations stated as a percentage of GDP (the general government includes the central government as well as additional public entities, such as state governments). More indebted countries are more likely to turn out incumbents. Public debt data are sources from the International Monetary Fund's (IMF's) World Economic Outlook (WEO)

Overall Budget Balance and *Primary Budget Balance*—which in this part of the analysis are independent variables but serve as our dependent variables in the second part of the analysis—are the sum of all general government revenues less expenditures stated as a percentage of GDP. A negative budget balance corresponds to a fiscal deficit. *Primary Budget Balance* strips out expenditures related to interest payments on national debt and better represents current incumbent government budget policies. Consistent with PBC models and evidence noted earlier, more negative budget balances increase the likelihood incumbent turnover. We source data for these terms from the IMF's WEO.

We also include two other political controls, both sourced from the DPI. *Unified Government* is a 0-1 indicator taking the value of 1 when legislative branches are led by the same party as the incumbent. Control of both legislative and executive branches makes election-period borrowing easier, which is positively related to incumbent turnover but is also controlled for with our budget balance terms. Aside from this, unified government also benefits incumbents by giving it greater ease in, for example, implementing electoral policies (e.g., voting age, place, manner, media access) beneficial to re-election prospects. We predict that *Unified Government* is negatively related to incumbent turnover.

Parliamentary System is also a 0-1 indicator taking the value of 1 when the country's head of state lacks substantial power to appoint the government ministers, lacks veto power over policy initiatives those ministers might pass through the legislature, and or lacks substantial independent power over government ministries such as, for example, foreign affairs. Of course, parliamentary systems also often permit the executive to choose the election date —call a snap election, for example— while presidential systems more often have fixed election dates. We bring no prior expectation regarding how this control will enter our model of incumbent turnover. Parliamentary System controls for any differences in incumbent turnover likelihood related to these contrasts in power allocation. We check for and exclude from our sample any apparent snap elections —as

identified either by the incumbents themselves or by outside observers like the International Foundation for Electoral Systems (IFES).

We sample only election years since we are interested in the effect of downgrades on incumbent electoral turnover. We require that elections be competitive. The DPI ranks executive elections on a 1 (not competitive) to 7 (competitive) scale. A score of 7 requires a multi-party system where at least one party contending in but not winning the election still polls at least 25% of the vote. We sample only from elections for countries with executive electoral systems ranked as a 7. We also adjust the election year for fiscal years when they do not coincide with the calendar year (Hanusch and Keefer, 2014). After screening our data based on these sampling and data availability requirements, we have a sample of 109 election-year observations from 53 countries observed from 2002-2011.¹

We estimate effects of *Downgrade* on *Incumbent Turnover* with the following model:

$$\begin{aligned} \text{Incumbent Turnover}_{it} = & \alpha_0 + \beta_1 \text{Downgrade}_{it} + \beta_2 \text{Downgrade}_{it-1} \\ & + \sum_{j=1}^{j=m} \psi_j \text{Controls}_{it,t-1} + \mu_{it} \end{aligned} \quad (1)$$

Incumbent Turnover in election-year t for country i is explained by *Downgrade*, various controls described above, intercept (α) and error (μ) terms. Since *Incumbent Turnover* is a 0-1 indicator, we use a probit estimator with robust standard errors clustered on countries. Time-varying macroeconomic controls (*GDP Growth*, *Ln GDP Per Capita*, *Public Debt*, *Primary Budget Balance*, *Overall Budget Balance*) are measured as two-year moving averages (t , $t-1$) to capture practical issues about when information relevant to voter decision-making is available. We assume that voters have access to macroeconomic data, but we cannot be sure whether it is actual and forecast data for year t or actual data for the previous year $t-1$. Thus, we take an average of the two periods. The theorized impact of *Unified Government* on voter outcomes permits assumption of an exclusively current-year (t) effect. The legislature and executive can implement (presumably advantageous) electoral policies in the election year.

Our hypothesis that rating downgrade increases the likelihood of incumbent electoral turnover will be supported if $\beta_1 > 0$ or $\beta_2 > 0$. We seek confirmation of any support for our hypothesis by replacing the downgrade terms with two alternatives indicating increased CRA regard for incumbent creditworthiness with a recent rating upgrade (*Upgrade*) or steady CRA regard with a stable rating (*Stable*). We expect these alternatives not to increase the likelihood of incumbent electoral turnover.

2.2. CRA Outlook and Electoral Budget Balance Analyses

Table 1 again lists model terms used in budget balance analyses (BBA). For these analyses, our primary dependent variable, *Budget Balance*, is either *Primary Budget Balance* or *Overall Budget Balance*. We use *Primary Budget Balance* first because it is likely better than *Overall Budget*

¹ Those 53 countries include: Argentina, Armenia, Australia, Austria, Bahamas, Belgium, Brazil, Bulgaria, Canada, Cape Verde, Chile, Costa Rica, Cyprus, Czech Republic, Denmark, Dominican Republic, Estonia, Finland, France, Germany, Greece, Grenada, Hungary, Iceland, India, Ireland, Israel, Italy, Latvia, Lithuania, Malaysia, New Zealand, Norway, Panama, Peru, Philippines, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Suriname, Sweden, Thailand, Trinidad and Tobago, Ukraine, UK, USA, Uruguay, and Venezuela.

Balance at approximating current incumbent fiscal policy decisions. Interest payments for past borrowing are non-discretionary and reflect past fiscal policies that the current incumbent may not have influenced. Focusing on the primary budget balances reduces one source of reverse causality in statistical estimations as high interest payments for past borrowing might also affect CRA perceptions of national solvency leading to a rating downgrade for reasons aside from current fiscal policy decisions. *Overall Budget Balance* is an alternative dependent variable measure used to assess the robustness of our initial findings.

Our three main independent variables for explaining variation in incumbent budget balances are *Rating*, *Election Year* and several rating “outlook” terms. *Rating* is the 2-year moving average of a country’s long-term foreign currency-denominated CRA rating on January 1 of current year and past year. Ratings summarize in ordinal letter-grade form CRA assessments of the ability and willingness of incumbents to meet their financial obligations. They summarize the impact of many macro-economic and political factors related this ability and willingness (Cantor and Packer, 1997) including those we noted in our description of the incumbent turnover model. As Table 2 illustrates, higher ratings indicate greater creditworthiness and greater access to capital for borrowing. We again use a 2-year moving average, this time to reflect practical issues about information available to incumbents. CRAs typically evaluate ratings annually, but we do not when that annual evaluation takes place. Thus, we attribute incumbent decision-making about budget balances to the average of the actual rating available at the beginning of year t and at the beginning of the previous year $t-1$. We expect that *Rating* will be negatively related to *Budget Balance*. *Election Year* is a 0-1 indicator taking the value of 1 in years when there is a national executive election. Consistent with opportunistic PBC theory, we expect that *Election* will be negatively related to *Budget Balance*. We source data on *Rating* from Bloomberg and data on *Election Year* from the DPI and IFES.

CRAs often give borrowing governments and the broader public notice when potentially changing ratings upward or downward. Notice could be that the rating is more amenable to change in the very short term –as short as over the next 6-8 weeks. Ratings are then on “watch” for upgrade or (more often) downgrade. Notice could also be that the rating is more amenable to change over a longer time horizon –over the next 1-2 years. Ratings then carry an “outlook” of a positive (for upgrade) or negative (for downgrade) category (Fitch, 2014).

With this in mind, we create three 0-1 indicators that take the value of 1 in election years when the rating is on negative watch or has a negative outlook (*Election Negative*), when the rating is on positive watch or has a positive outlook (*Election Positive*), when the rating is neither on watch or has no outlook (*Election Stable*). Consistent with our hypothesis that incumbent governments will borrow less when CRAs indicate increased willingness to downgrade in during an election period, we expect that *Election Negative* will be positively related to *Budget Balance*. By contrast, we expect that *Election Stable* and *Election Positive* will be negatively related to *Budget Balance*. When we interact these election-year outlook dummies with *Rating* (*Election Negative x Rating*, *Election Stable x Rating*, *Election Positive x Rating*), these three terms capture effects on *Budget Balance* at very low rating levels while the interaction terms indicate how those effects are magnified or diminished with increasing election-year creditworthiness. We source these data from Bloomberg.

We again include several controls that might also affect budget balances including (expected effect): *GDP Growth* (+), *Ln Per Capita GDP* (+), *Public Debt* (-), *Unified Government* (-) and

Parliamentary System (-).² Table 1 again elaborates on their measurement, including the 2-year moving average measurement of the macro-economic controls, and their descriptive statistics in our budget balance analyses. We also include country (δ') and year (ϕ') fixed effects, and a lagged dependent variable, *Budget Balance*_{*t-1*}, to control for other unspecified past factors potentially affecting current-year primary budget balances.

For these analyses, we sample from a slightly larger number of countries and can include observations from both election and non-election years. We have 460 country-year observations from 63 countries holding 111 elections from 2002-2011.³ We initially estimate effects of elections, ratings and rating outlooks on budget balances with the following model:

$$\begin{aligned} \text{Budget Balance}_{it} = & \alpha_0 + \beta_0 \text{Budget Balance}_{it-1} + \beta_1 \text{Rating}_{it,t-1} \\ & + \beta_2 \text{Election Year}_{it} + \sum_{j=1}^{j=m} \psi_j \text{Controls}_{it,t-1} + \delta' + \phi' + \mu_{it} \end{aligned} \quad (2)$$

Budget Balance in year *t* for country *i* is first explained with a 1-year lagged value of *Budget Balance* and then *Rating*, *Election Year*, various controls (*Controls*) described above, country (δ') and year (ϕ') fixed effects, an intercept (α) and error (μ) terms. Again, we use *Primary Budget Balance* as our primary dependent variable because it is a better measure of current incumbent fiscal policy. *Overall Budget Balance* is our alternative measure; it includes expenditures for interest on past budget deficits stripped out of the *Primary Budget Balance* number. We expect that both ratings and elections prompt more borrowing by incumbents, thus $\beta_1 < 0$ and $\beta_2 < 0$.

We then re-specify (2) to account for election year rating outlooks so that we can test our hypothesis that a negative outlook decreases incumbent borrowing in election years lest CRAs downgrade incumbents undercutting claims of good economic stewardship on the campaign trail, and perhaps, raising the cost of borrowing. Estimated effects of elections, ratings and rating outlooks on budget balances follows from this revised model:

$$\begin{aligned} \text{Budget Balance}_{it} = & \alpha_0 + \beta_0 \text{Budget Balance}_{it-1} + \beta_1 \text{Rating}_{it,t-1} \\ & + \beta_{2A} \text{Election Positive}_{it} + \beta_{3A} \text{Election Stable}_{it} + \beta_{4A} \text{Election Negative}_{it} \\ & + \sum_{j=1}^{j=m} \psi_j \text{Controls}_{it,t-1} + \delta' + \phi' + \mu_{it} \end{aligned} \quad (3)$$

Our hypothesis will be supported if $\beta_{3A} > \beta_{1A}$ or $\beta_{3A} > \beta_{2A}$, which would indicate that election-year borrowing by incumbents is decreases with a negative outlook compared to when its rating is either stable or has a positive outlook. Given our expectation of increased borrowing in an election year, our hypothesis will also find support if $\beta_{3A} > 0$, that is, incumbent borrowing is decreased (not increased) when CRAs have indicated a heightened willingness to downgrade with a negative outlook.

² The inclusion of the *Unified Government* variable follows the logic laid out in Hanusch 2012 (a, b).

³ Those 63 countries include: Argentina, Armenia, Australia, Austria, Bahamas, Belgium, Botswana, Brazil, Bulgaria, Canada, Cape Verde, Chile, Costa Rica, Croatia, Cyprus, Czech Republic, Denmark, Dominican Republic, Estonia, Finland, France, Germany, Greece, Grenada, Guatemala, Honduras, Hungary, Iceland, India, Ireland, Israel, Italy, Japan, Kenya, Latvia, Lesotho, Lithuania, Malaysia, New Zealand, Nigeria, Norway, Panama, Peru, Philippines, Poland, Portugal, Romania, Russia, Slovakia, Slovenia, South Africa, Spain, Suriname, Sweden, Thailand, Trinidad and Tobago, Turkey, Ukraine, UK, USA, Uruguay, and Venezuela.

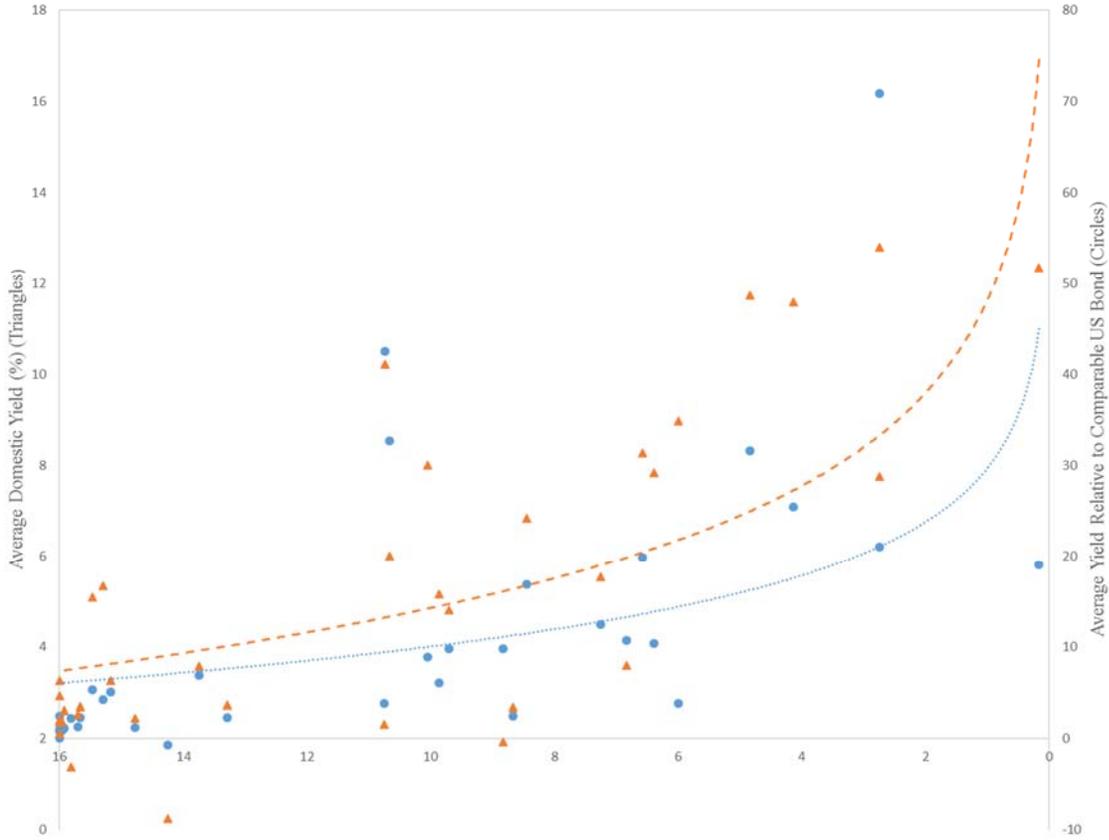

We then re-specify (2) yet again, this time to account for any election-year outlook effects on incumbent borrowing that may be conditioned by the ordinal level of incumbent financial creditworthiness. It may be that heightened willingness to downgrade incumbents has a magnified affect when, for example, incumbent ratings are at the highest level, AAA (16). During the French presidential election campaign of 2011-2012, incumbent Nicholas Sarkozy correctly predicted that losing this top rating would contribute to his defeat on election day: “If France loses its AAA, I'm dead” (Guardian, 2012). This conjecture relies on the negative signaling effect of downgrade from the highest possible letter-grade ranking by an outside expert organization.

It could also be that the outlook effect on election-year borrowing is stronger at the lower end of the rating scale, that is, below the cut-off between investment and non-investment “junk” ratings (BBB- = 7 and BB+ = 6). Here, the conjecture relies on the negative signaling effect of downgrade by an outside expert, but now in the context of a developing democracy seeking to establish some basic reputation for creditworthiness where internal institutional checks and balances assuring fiscal responsibility are poor or altogether absent. We have no *ex ante* expectation regarding which signaling effect—at the top or bottom of the rating scale— may be stronger.

The other disciplining mechanism for CRAs relates to their purported ability to affect change in the cost of capital with a downgrade. Figure 1 below depicts evidence consistent with this view. It plots and then derives a curvilinear trend line on ratings and sovereign bond yields absolutely and relative to comparable US bonds for 1-year bonds offered by 37 countries in our sample from 2001-2011.⁴ The negative relationship between rating and sovereign bond yield is more pronounced below than above the investment-junk grade rating cutoff, suggesting that this alternative mechanisms for disciplining incumbents may be more pronounced for developing democracies struggling to establish some basic reputation for creditworthiness rather than for developed democracies at the higher end of the rating scale:

⁴ Those 37 countries include: Argentina, Australia, Austria, Belgium, Brazil, Bulgaria, Canada, Chile, Colombia, Croatia, Czech Republic, Denmark, Finland, France, Germany, Greece, Hungary, India, Ireland, Italy, Japan, Kenya, Latvia, Lithuania, New Zealand, Norway, Poland, Portugal, Romania, Russia, Spain, Sweden, Thailand, Turkey, Ukraine, UK, and USA.

FIGURE 1: Average annual CRA rating and bond yield on 1-year sovereign bonds, 2001-2011

To probe for these effects at different ends of the rating scale, we define the following revised model:

$$\begin{aligned}
 \text{Budget Balance}_{it} = & \alpha_0 + \beta_0 \text{Budget Balance}_{it-1} + \beta_1 \text{Rating}_{it,t-1} \\
 & + \beta_{2A} \text{Election Positive}_{it} + \beta_{3A} \text{Election Stable}_{it} + \beta_{4A} \text{Election Negative}_{it} \\
 & + \beta_{5A} \text{Election Positive} * \text{Rating}_{it} + \beta_{6A} \text{Election Stable} * \text{Rating}_{it} \\
 & + \beta_{7A} \text{Election Negative} * \text{Rating} + \sum_{j=1}^{j=m} \psi_j \text{Controls}_{it,t-1} + \delta' + \phi' + \mu_{it}
 \end{aligned} \tag{4}$$

Now, the election-year rating outlook dummies capture incumbent borrowing effects when rating levels are near the investment-non-investment grade cut-off at the lower end of the rating scale; their associated interaction terms capture changes in effects as the rating level increases indicative of greater incumbent creditworthiness. Again, we look for whether incumbents reverse an election-year tendency to borrow more ($\beta_{3A} < 0$) or that election-year borrowing with that negative outlook is decreased compared to borrowing in election years with stable or positive rating outlook ($\beta_{3A} > \beta_{1A}$ or $\beta_{3A} > \beta_{2A}$).

We have panel data, so we initially estimate (2) with panel fixed effects regression. We then re-estimate (2-4) with a dynamic panel generalized method of moments (GMM) with robust standard errors based on Arellano and Bover (1995) and Blundell and Bond (1998), and implemented with a Stata add-on program written by Roodman (2006). Estimating lagged dependent variable effects in a panel estimation with fixed country effects can lead to downwardly biased estimates where

the time series is limited, that is, less than approximately 30 time periods. Our panel GMM estimator corrects for this so-called Nickell (1981) bias, by first-differencing the equation to eliminate fixed country effects and then generating instruments in the form of lagged differences and levels of the lagged dependent as well as other right-hand side terms deemed to be endogenously determined. This “system-and-difference” GMM estimator is more appropriate than a “difference” GMM estimator (Arellano and Bond, 1991) given the broad cross-sectional -63 countries- but relatively short within-panel time series –about 7 observations per country on average. For all panel GMM estimations, we test for both the exogeneity of instruments as a group generated and for the presence of higher (than first-order) autoregressive processes that might otherwise bias estimates.

3. Results

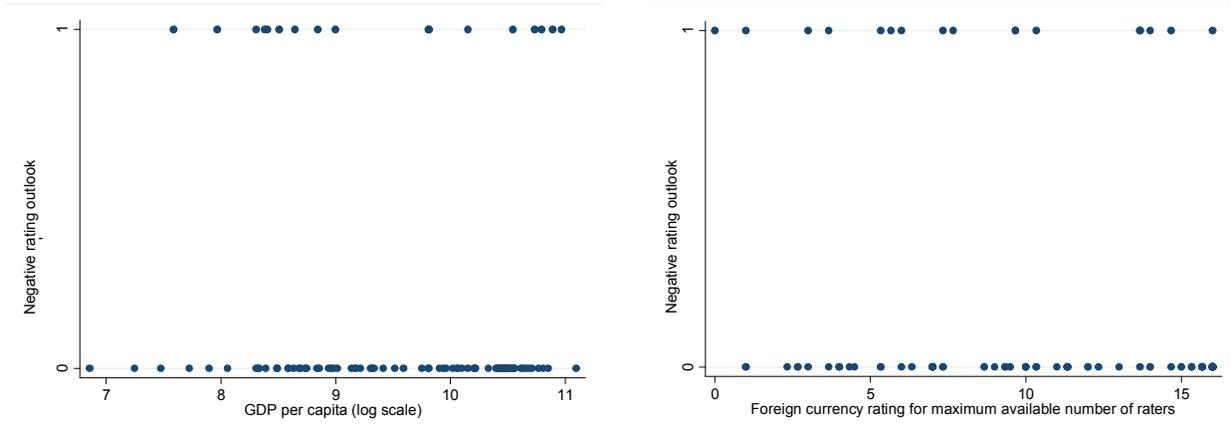

3.1. Descriptive Statistics and Preliminary Analyses

Table 1 reports means and standard deviations for our ITA and BBA samples, which exhibit close comparability. The means for *Rating* in the ITA sample (10.92) and BBA sample (10.44) both lie between A- and A in Table 2, while *Primary Budget Balance* means and standard deviations in the ITA (-0.35 and 4.13) and BBA (-0.37, 4.20) samples are nearly identical. At first glance, CRA ratings and budgeting dynamics they may influence generally show few differences in election years covered by the ITA sample versus the broader ranged BBA sample comprising both election- and non-election years.

Other descriptive statistics for each sample convey helpful preliminary insight related to our two hypotheses. Regarding the ITA sample, we first note the distribution of recently downgraded versus recently upgraded or stable ratings going into an election year. Downgrades are relatively rare, only 9% of our 109 election-year observations. Compare this to 63% with stable ratings and 28% with recent upgrades going into an election year. These descriptive statistics follow a broader long-term trend of increasing sovereign creditworthiness and, perhaps, rating optimism among CRAs. In the BBA sample, about one third of the election-year observations have outlooks attached to them and the split between negative (18%) and positive (15%) is close.

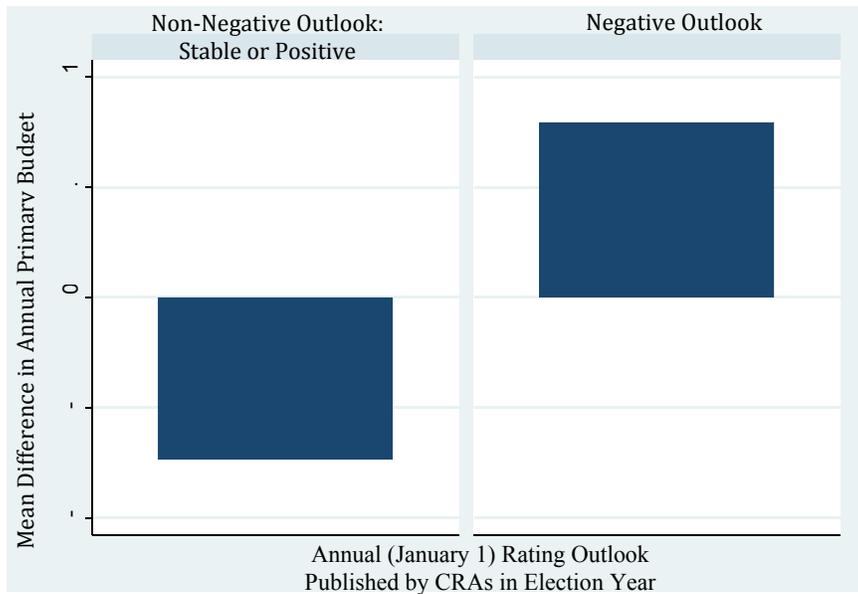

Another interesting property of our BBA sample is illustrated in Figures 2a-b, which plot election-year observations with a negative outlook against log of GDP per capita (Figure 1a) and average rating (Figure 1b). Outlooks in both figures as well as others using other control variables suggest that outlooks are well distributed across dimensions commonly associated with a country’s level of development and financial solvency. These preliminary analyses assure against detection of spurious relationships between election-year rating outlook and budget balance effects. This assurance is particularly valuable in our final set of analyses where we interact election-year outlooks with rating levels in (4).

FIGURE 2a-b: Negative outlook (1) versus non-negative outlook (2) election-year observations grouped by GDP per capita and average CRA rating, 2002-2011

A final preliminary analysis provides initial insight on our hypothesis regarding the budget balance impact of outlooks in election years. Figure 3's bar chart compares year-to-year changes in *Primary Budget Balance* for the 111 election years in our BBA sample.

FIGURE 3: Change in the primary budget balance in election years under negative versus non-negative rating outlook, 2002-2011

The contrast is clear and in line with our hypothesis that incumbents with negative (non-negative) outlooks run less (more) negative budget balances in election years. Incumbents with “non-negative” rating outlooks can borrow for political purposes with less threat of downgrade and ouster at the polls.

3.2. Regression Results: Incumbent Turnover Analyses

Table 3 reports results from cross-sectional probit regression of *Incumbent Turnover* on different combinations of control and main variables listed in Table 1. Recall here that our hypothesis is that recent CRA downgrades undermine incumbent attempts to signal good economic stewardship to voters in election years and thus increase the likelihood that the incumbent will be turned out of office that year. Column 1 presents results from probit regression with control variables only and *Primary Budget Balance* as the budget balance control. Recall, too, that we made no prediction regarding how the electoral system would affect incumbent turnover likelihood. For the other five controls, coefficient estimates in Column 1 exhibited the predicted sign at commonly-accepted levels of statistical significance ($p < 0.10$) in four instances. Incumbents in richer countries experiencing unified government are also less likely to be turned out of office that year. Moreover, incumbent turnover is less likely in countries with less public debt and lower fiscal deficits, a notion supporting the idea that sound fiscal stewardship is rewarded by voters (a result mirroring the findings of Brender and Drazen (2008)).

Columns 2-3 add *Downgrade* (and *Downgrade_{it-1}*) to equation (1) with Column 3’s results based on the substitution of *Overall Budget Balance* for *Primary Budget Balance*. Results support our hypothesis that a recent downgrade imperils incumbent re-election. In Column 2 (0.767, $p < 0.10$) and Column 3 (0.817, $p < 0.10$) *Downgrade* enters with the expected positive sign at commonly-accepted levels of statistical significance. Note that this effect applies separately from other fiscal controls, suggestive of the interpretative power of “opinions” CRAs offer on fiscal sustainability to the general public through their ratings.

In Column 4, we estimate marginal effects of a 1-unit change in all terms of equation (1) based on Column 2 results. Here it is helpful to recall that the mean for *Incumbent Turnover* is 0.52, meaning that incumbents lose office on in election years about 52% of the time for our 53 countries from 2002-2011. A recent downgrade increases that likelihood by 27 percentage points (0.270, $p < 0.10$) holding other variables in equation (1) at their mean levels. This increase is substantial, although it is important to note that it is estimated with only a handful (10) of actual downgrades in the sample, indicating that downgrades are rare events.⁵

Columns 5-6 implement the same estimations of equation (1) but in Column 5 after switching in *Stable* and in Column 6 after switching in *Upgrade* for the *Downgrade* term. The negative sign and significance of the *Stable* term in Column 5 (-0.465, $p < 0.10$) suggests that incumbents with stable ratings are somewhat more likely to be re-elected. Going into the election campaign with a recent upgrade has no significant effect on re-election. These contrasts indicate additional support for our hypothesis that CRAs can punish incumbents through downgrades that would undercut claims of good stewardship signaled by expansionary fiscal policy.

⁵ We also find some evidence suggesting that rating changes for countries with investment grade ratings have a particularly pronounced effect on election results. However, the number of downgrades in our sample is too small for any authoritative inferences on the effect of rating downgrades differentiated by investment/junk grade.

3.3 Regression Results: Budget Balance Analyses

Table 4 reports results from panel fixed effects estimation (Column 1) and then dynamic panel GMM estimation (Columns 2-6) of budget balances in and out of election years with different ratings and rating outlooks. Recall here that our hypothesis is that, in election years, ratings with a negative outlook indicate heightened likelihood of a downgrade by CRAs that will prompt incumbents to run smaller fiscal deficits (*i.e.*, less negative budget balances). In Table 4, the dependent variable in Columns 1-4 is *Primary Budget Balance* while in Columns 5-6 it is *Overall Budget Balance*. We use a lagged dependent variable in all estimations along with control variables used in our previous incumbent turnover analyses.

Columns 1-2 report basic results from estimation of equation (2), which includes lagged dependent variables, controls, *Rating* and *Election Year* terms. Initially, our aim is to probe for PBC effects and confirm the appropriateness of our panel GMM estimation strategy. With panel fixed effects regression in Column 1, we find that the lagged dependent variable is positive, lies between 0 and 1, and is significant at commonly-accepted levels (0.486, $p < 0.01$). Last year's *Primary Budget Balance* explains approximately half of the variation in the current-year's *Primary Budget Balance*. Again, we have no prediction regarding the sign on the electoral system indicator (*Parliamentary System*), but observe expected signs on three of the four other control variables. None is significant at commonly-accepted levels of statistical significance, which is not unusual in a lagged dependent variable setting with country and year fixed effects included (though not reported).

In Column 1, *Rating* (-0.557, $p < 0.10$) and *Election Year* (-0.392, $p < 0.05$) enter with the expected negative signs. These results follow Hanusch and Vaaler (2013), who also show that higher ratings are associated with stronger solvency indicators, likely the consequence of more prudent fiscal stewardship. Accordingly, larger deficits can be sustained without threatening national solvency. Moreover, lower borrowing costs associated with higher ratings reduce the relative cost of deficit-spending. In election years, incumbents with higher ratings borrow less, which may follow from a fear of downgrade or other motivations to remain fiscally responsible, even when facing the possibility of ouster by voters. Results in Column 1 are consistent with such interpretations and explain more than 62% of the variation in budget balances in doing so.

Column 2 re-estimates equation (2) with the dynamic panel GMM procedure. The jump in the estimate of the lagged value of the *Primary Budget Balance* from 0.486 to 0.689 ($p < 0.01$) means that downward bias is being adjusted up as expected with the dynamic panel GMM procedure. Now all four controls for which we have predicted signs exhibit those signs though not at commonly-accepted levels of significance. *Rating* again enters with the predicted negative sign but now only at the 12% level of significance. *Election Year* again enters negatively and significantly (-0.366, $p < 0.10$), documenting the existence of PBCs in our sample. Other dynamic panel GMM diagnostic data follow expectations. We do not reject the null hypothesis of second or higher order autocorrelation based on the Arellano-Bond test statistic (0.73), nor do we reject the null hypothesis that the 79 instruments we generate are exogenous as a group based on the Hansen test statistic (0.87). Consistent with our hypothesis, we next investigate whether and how the PBC effects we detect differ under positive, stable and negative outlooks.

Dynamic panel GMM results in Columns 3-4 yield important insight regarding that investigation. In Column 3, we replace Election Year with the three election outcome variables highlighted in equation (3). *Election Negative* takes the value of 1 when it is an election year and the incumbent rating has a negative outlook indicating a higher likelihood of near-term downgrade. As expected, *Election Negative* enters with a positive sign (0.201) but is not significant at commonly-accepted levels. By contrast, both *Election Stable* (-0.524, $p < 0.05$) and *Election Positive* (-0.495) are negative with *Election Stable*'s estimate significant at the 5% level. Incumbents with stable ratings going into an election do borrow significantly more than in non-election years.

One way to demonstrate support for our hypothesis about election-year borrowing and rating outlook is by direct examination of the sign and significance of the *Election Negative* coefficient. Based on this test, we cannot conclude significant support in Column 3. We also cannot conclude support in Column 3 based on an alternative test that compares the coefficient estimate for *Election Negative* with that for *Election Stable* and *Election Positive*. Results from those comparisons are given in Table 4. Neither the *Election Negative-Election Stable* (0.41) nor the *Election Negative-Election Positive* comparison test statistics are statistically significant at commonly-accepted levels.

To investigate these differences further, we partition election outlook effects by rating level consistent with equation (4). Now, *Election Negative*, *Election Stable* and *Election Positive* terms capture effects on *Primary Budget Balance* of differing outlooks when the underlying rating is very low, meaning in the non-investment “junk” range (*i.e.*, less than BBB-). At these low ratings, we can again tease out whether there are statistically significant differences between negative outlooks in election years compared to positive or stable outlooks. Table 5 demonstrates that at these low rating levels, the differences are significant. Incumbents borrow less when they are on negative rating watch. This result holds for our samples using both the *Primary Budget Balance* and the *Overall Budget Balance*

4. Conclusion

We set out in this study to understand whether and how CRAs and their ratings might influence rather than merely reflect election-year fiscal policies of incumbents. We found evidence broad-sample evidence of that influence. Downgrades going into election years increase the likelihood that incumbents will lose at the polls from 52-nearly 80%. Heightening the threat of a downgrade with a negative outlook appended to ratings going into an election year means that incumbents with low ratings borrow no more in than out of election years. Ratings and the CRAs that publish them can significantly and substantially affect incumbent fiscal policy behavior and electoral prospects. Ratings act like other rules that constrain PBC tendencies and provide fiscal discipline to incumbents that otherwise face immediate negative electoral and longer-term negative financial effects if downgraded.

Our findings matter for PBC research. With the exception of Hanusch and Vaaler (2013), PBC researchers have either ignored CRAs as relevant players in election-year fiscal policy or treated them as mere observers of respondents to incumbent decisions (*e.g.*, Block and Vaaler, 2004). Our study

suggests that CRA ratings may play an important role in diminishing PBC tendencies to engage in wasteful, electorally-motivated spending sprees. Future PBC research should incorporate such CRA influence, particularly where that research includes developing democracies with lower ratings or even no ratings if the incumbent has evinced interest in greater financial openness.

Our findings also matter for public policy related to CRAs and their influence on incumbents during election periods. Conspicuous failures by CRAs to warn investors of fiscal crises in many developing democracies of the 1990s (*e.g.*, Russia) and then developed democracies in the 2000s (*e.g.*, Greece) have contributed to calls by many to decrease reliance on CRAs and their ratings for international lending purposes (White, 2010). By contrast, our study suggests that CRA ratings anticipate and diminish wasteful election-year spending sprees with a mix of threatened and actual downgrades. They provide helpful fiscal discipline and encourage borrowing for public infrastructure and social program investments that support longer-term economic growth and poverty reduction. Just as CRAs merit criticism by policy makers for their failure to anticipate and diminish the effects of occasional financial crises, CRAs may also merit some commendation for apparent success at anticipating and diminishing the effects of more frequent and potentially crisis-inducing elections in democracies around the world. Future research should ask whether and how these successes may be contingent on other factors related to the CRA industry –for example, how many CRAs rate an incumbent during election years- or related to the type of election involved –for example, whether CRA ratings and outlooks also moderate election-year borrowing by incumbents in state and local elections.

Our findings also matter for executives working at CRAs and related financial institutions assisting incumbents in their efforts to raise capital internationally. Senior executives at CRAs have been silent about the influence their ratings have on incumbents, particularly after one CRA was sued in the 2010s by US federal and state agencies for alleged fraud in rating bonds secured by home mortgages and other financial assets that lost substantial value and caused substantial financial losses to investors during the Great Recession (Department of Justice, 2015). Rating with an alleged intent to influence led then to law suits and legal settlement costing the CRA nearly \$1.4 billion. We make no claims that the sovereign ratings analyzed in this study were published with the intent to influence incumbent fiscal policy during election periods. We assume that their disciplining impact is inadvertent. But no matter the intent, CRA opinions carry substantial weight that executives should acknowledge and thus render only after careful review of risk factors, a review that may be more costly for any borrower, sovereign or not, after this recent legal settlement.

Future research should investigate CRA review as well as government regulatory processes to understand when and where ratings might be more vulnerable to bias. For example, Vaaler and McNamara (2004) have documented significant and substantial negative bias in CRA ratings for several developing countries in the aftermath of the so-called Asian Financial Crisis of 1997-1998. They demonstrate that the more negative (than rating fundamentals suggest) assessments of sovereign creditworthiness are tied to different industry position of and competitive rivalry among certain CRAs, including those analyzed in our study. Perhaps, future research might treat elections as a form of constitutionally-mandated political crisis that could prompt more negative assessments of sovereign creditworthiness magnified by competition among the CRAs for rating business in such countries. These “second-order” rating dynamics might also figure prominently in incumbent fiscal policy during election years. In any case, the aim of such follow-on research should be to increase our understanding of CRA ratings that not merely reflect but also substantially influence election-year finance and politics around the world.
